DECLARATION

Declaration, copyright statement and the statement of the supervisor

“I declare that this is my own work and this thesis does not incorporate without acknowledgement any material previously submitted for a Degree or Diploma in any other University or institute of higher learning and to the best of my knowledge and belief it does not contain any material previously published or written by another person except where the acknowledgement is made in the text.

Also, I hereby grant to University of Moratuwa the non-exclusive right to reproduce and distribute my thesis, in whole or in part in print, electronic or other medium. I retain the right to use this content in whole or part in future works (such as articles or books)”.

Signature: 

Date: 22/12/2020

The above candidate has carried out research for the MPhil Thesis under my supervision.

Name of the supervisor: Dr. Thanuja Ramachandra

Signature of the supervisor: Date: 23/12/2020

DEDICATION

I dedicate this thesis to my beloved family...

ACKNOWLEDGEMENT

There were many persons, who were of great importance and influence to me throughout the period in which this thesis was developed, whom I would like to acknowledge most gratefully.

First and foremost, I owe my heartfelt gratitude towards my supervisor, Dr. Thanuja Ramachandra, for all the excellent supervision, continuous encouragement, assistance, and gentle guidance put forward to make this study a success. Further, my sincere gratitude goes to Dr. Anupa Manewa, Senior Lecturer, School of Civil Engineering and Built Environment, Liverpool John Moores University, UK and Assoc. Prof. Niraj Thurairajah, Senior Lecturer, Department of Architecture and Built Environment, Northumbria University, UK as progress reviewers for their constructive feedback to make this research a fruitful one.

I wish to extend my utmost gratitude to Prof. Yasangika Sandanayake, Head, Department of Building Economics, Dr. Sachie Gunatilake, Research Coordinator, and all the other academic and non-academic staff members of the Department of Building Economics for their enormous advice and assistance during the course of this MPhil study. In addition, I appreciate the technical support received from Mr. A.A.D.W.V. Udayashantha. I further gratitude to the Postgraduate Studies Division in the Faculty of Architecture and the Faculty of Graduate Studies for their support.

I must express my greatest appreciation to all the professionals in the industry who contributed to this study by actively participating and sacrificing their valuable time in data collection process despite their busy work schedules.

I gratefully acknowledge the funding received towards my MPhil from the Senate Research Committee Grant, University of Moratuwa.

Last but not least, I am forever indebted to my beloved parents, husband, and brother for their unconditional love, emotional sacrifices, and for their constant help and encouragement, without which I would have never realised my objectives.

Certainly, many others extended their support in numerous ways to make my PhD journey successful. I am grateful to all of them.

ABSTRACT

A model for forecasting the running costs of commercial buildings in Sri Lanka

Conventionally, early-stage investment decisions on buildings were purely based on initial capital costs and simply ignored running costs and total lifecycle cost. This was basically due to the absence of estimating models that yield running costs at the early design stage. Often, when the design of a building, which is responsible for 10 to 15% of its total cost, is completed, 80% of the total cost is committed. This study, therefore, aims to develop a model based on building characteristics, which enable an early-stage determinant of running costs of buildings, to predict the running costs of commercial buildings. While positioning this research in a positivist research paradigm, a survey research strategy was adopted along with a questionnaire survey and a documentary review for data collection. The study involved 135 respondents for identifying factors influencing the running costs of commercial buildings and 46 commercial buildings were accessed to collect running costs and building characteristics data. A Pareto analysis, relative significance index (RSI), bivariate correlation analysis, regression modelling, and hedonic price imputation index were performed on collected data. The RSI confirmed, eight categories of running costs factors: environmental, maintenance, managerial, building characteristics, building design and construction defects, social, tenant, and political, respectively. Among 48 sub-factors identified, the study confirmed, natural deterioration, failure to identify the true cause of a defect, lack of preventive maintenance, insufficient fund, building services, building age, occupancy, vandalism by tenants, misuse of property, expectation of tenants have a substantial impact on running costs. According to the Pareto analysis, utilities (39%), services (19%), admin work (14%), and cleaning (8%) are four main cost constituents, responsible for 80% of running costs, which can be represented by highly correlated building characteristics of the number of floors (0.950), building height (0.945), and building size (0.943). Approximately 94% of the variance in annual running costs/GIFA (sq.m) is expressed by variables of net floor area, the number of floors, and working hours/day together with a mean prediction accuracy of -1.6%. The index constructed revealed, there is an increasing trend of running costs of commercial buildings in Sri Lanka, in office and bank buildings particularly, over the last recent years. Further, a noticeable increase in running cost can be observed during the first quarter while there is a slight reduction in the second quarter of each year. Early-stage supportive running costs estimation model proposed by the study would enable construction professionals to benchmark the running costs and thereby optimise the building design. The developed hedonic model illustrated the variance of running costs concerning the changes in characteristics of a building. While facilitating early-stage running costs estimation, the study findings collectively support building owners, designers and constructors, and facilities managers to optimize the in-use phase costs of a commercial building in terms of designing and constructing cost-effective, sustainable facilities by altering building characteristics during its' design stage as well as carefully considering the significant running costs factors during its' in-use phase.

Keywords: Building characteristics, Commercial buildings, Hedonic price imputation index, Regression modelling, Running costs
