PREFACE

The study described in this report was carried out as a part of the course requirements for a Master's degree in Hydrology and Water Resources Engineering. The course was sponsored by the UNESCO and conducted at the University of Moratuwa, Sri Lanka. The course coordinator was Prof. V.C. Kulaindaswamy, UNESCO advisor to the dept. of Civil Engineering. Prof. Kulaindaswamy assisted by a few visiting lecturers handled the entire teaching work in the course. The author completed the examination requirements for the Master's degree by January 1981 but could not start on a research project for some time as there was no supervisor to guide him at the time. When Dr. D.C.H. Senarath came back to the department after his sabbatical leave in March 1981 he kindly agreed to supervise this study.

After a few months of works in data collection, debugging of computer program etc. the author had to suspend his work due to the break down of the University computer system. Subsequently the computation work was completed while the author was studying at the International Institute for Hydraulic and Environmental Engineering (I.H.E.) Delft, the Netherlands.

In the study no attempt has been made on the development of mathematical aspect of the model. All the emphasis was placed on studying the behaviour of the aquifer with different sets of data which were compiled on the basis of available records as well as on a number of assumptions.

The historical data available was not long enough even for proper calibration of the model. Therefore the verification of the model could not be attempted.

ACKNOWLEDGEMENTS

The author wishes to place his deep gratitude towards Prof. V.C.Kulaindasamy for his untiring efforts to teach in the Post Graduate course which the author had followed in the field of Hydrology. Dr. D.C.H.Senarath spent his valuable time in supervising the project, without his continuous guidance the author would not have been able to complete this work.

Mr. M.W.P.Wijesinghe, the former Deputy General Manager, Water Resources Board of Sri Lanka has authorised the use of their records for the study. He has made valuable suggestions for the study and the author has benefited much from his wide experience in the field of Groundwater Hydrology. Mr. J. Davis, consultant and Mr. W.P.Rodrigo, technical assistant of the Water Resources Board provided help in collecting data.

 The staff of the computer centres at University of Moratuwa and I.H.E. Delft provided much assistance in carrying out computations.

University of Moratuwa, Sri Lanka.
Electronic Theses & Dissertations
www.lib.mrt.ac.lk

Dr. K.R.Rushton of Birmingham University and Mr. W. Spaans of I.H.E.Delft made valuable comments to improve this work.

The help and moral encouragements extended by Prof. Willie Mendis, Vice Chancellor, University of Moratuwa and Prof. B.L.Tennekoon, Head of Civil Engineering department are deeply appreciated. Thanks are extended to all the staff members of the Department of Civil Engineering who in numerous ways helped to carry out this work.

SUMMARY

Modelling of a limestone aquifer in the north west of Sri Lanka is attempted. The Vanathavillu basin situated 10 km. north of Puttalam, covering an area of approximately 50 sq.km. has been studied using a mathematical model based on an implicit finite difference scheme. The study area situated in the dry zone of Sri Lanka, receives a seasonal rainfall of about 900 mm/year, the most of which falls during the months of October to December.

In the Vanathavillu basin there are essentially two water bearing formations:

- the miocene sedimentary strata.
- the quarternary deposits which overlie the miocene strata. (referred as Moongil Aru formation)

Moongil Aru formation consists of a series of clays and silts which partly confines the miocene formation. The piezometric levels in the miocene aquifer is lower than the phreatic surface by up to 30 m in the central parts of the region. In the north the piezometric levels are slightly higher than the phreatic surface. The two water bearing formations are interdependant as leakage takes place in and out of the miocene formation. The model was developed only for the miocene formation and the water table elevations in the Moongil Aru formation assumed constant.

The miocene formation is bounded in the east by basement rock outcrops which are relatively impermeable. To the west a fault exists which runs along the coast line. This fault restricts the flow in westerly direction. It is believed that two minor faults exists along two drainage paths of Kala Oya and Moongil Aru. The piezometric levels in the north suggest that the aquifer discharges into Kala Oya which could be treated as a constant head boundary. In the south the flow direction is entirely towards north.

The area has been studied by the Irrigation Dept. and the Water Resources Board of Sri Lanka. On the basis of these investigations aquifer parameters, recharge and abstraction from the limestone aquifer have been estimated. Development plans have been prepared

on the basis of these estimates. The purpose of the present model investigation was to assess the reliability of these estimates and also to provide a tool for planning future development and management of this valuable water resource.

A number of model runs with different sets of data representing aquifer parameters, boundaries and flows were made. The results were compared with an available two year record of piezometric levels in the limestone aquifer. Computations were made with one layer model as well as with a simple two layer model.

A single layer model with constant inflows or a simple two layer model with water table elevation treated as a constant adequately describe the behaviour of the aquifer under the present level of abstraction. But the behaviour of the aquifer with highly increased abstraction can only be modeled adequately by a two layer model representing both unconfined and semiconfined aquifers together.

TABLE OF CONTENTS

Preface	i
Acknowledgements	ii
Summary	iii
List of figures	v
List of tables	vii
Chapter 1. Introduction	1
1.1 Location	1
1.2 Topography	1
1.3 Geology	1
1.4 Water bearing formations	2
1.5 Hydrological system	2
1.6 Need for modelling	3
1.7 History of the investigation	4
1.8 Scope of the study	4
1.9 Source of data	5
Chapter 2. Use of mathematical models to investigate groundwater systems	14
2.1 General	14
2.2 Types of models	15
2.3 Physical scale models	15
2.4 Analogue models	15
2.5 Mathematical models (Analytical)	16
2.6 Mathematical models (Numerical)	17
2.7 Finite difference models	18
2.8 Finite element models	18
2.9 Polygon methods	19
Chapter 3. Formulation of finite difference model	20
3.1 Basic concepts	20
3.2 Governing equations	21
3.3 Idealisation of regional groundwater flow	22
3.4 Finite difference equations	22
3.5 Backward difference formulation	23
3.6 Convergence criteria	26

Chapter 4. The groundwater model	28
4.1 Basic features	29
4.2 Rectangular grid	29
4.3 Boundary conditions	29
4.4 Programming of boundary conditions	29
4.5 Aquifer parameters	31
4.6 Inflows and outflows	31
4.7 Computations	32
4.8 Definitions of important variables.	32
4.9 Input description	33
4.10 Output description	37
Chapter 5. Hydrogeological description of the area	40
5.1 Boundaries	40
5.2 Recharge	41
5.3 Radial flow model to analyse pump tests	41
5.4 Water balance for water table aquifer	41
5.5 Water balance for limestone aquifer	44
5.6 Leakage from limestone aquifer	45
5.7 Transmissivity and storage coefficient	45
5.8 Abstraction from the limestone aquifer	46
Chapter 6. Results of the model runs	55
6.1 General remarks	55
6.2 Geometry of the aquifer boundary	55
6.3 Sensitivity analysis	55
6.4 Model runs for Vanathavillu aquifer	58
6.5 Results of the model runs for Vanathavillu aquifer	60
6.6 Model runs with different boundary conditions	60
6.7 Model runs with different inflows and outflows	62
6.8 Results of the two layer model	64
Chapter 7. Conclusions and recommendations	83
7.1 Aquifer system	83
7.2 Aquifer parameters	83
7.3 Inflows and Outflows	84
7.4 Potential for development	84
7.5 Recommendations	84
